

## Project No. AS – 42

**Title:** Agronomic evaluation of promising sugarcane genotypes (Spring Early)

- Objective:**
- 1) To find out the suitable sugarcane genotypes for early spring planting.
  - 2) To find out suitable sugarcane genotypes for highest cane and CCS yield.
  - 3) To find out the suitable fertilizer dose for promising sugarcane genotypes.
  - 4) To find out suitable interaction of promising sugarcane genotypes and fertilizer dose for highest cane and CCS Yield.

### Experimental Details:

Place	: CSRS, Padegaon,
Design	: Split plot
Replication	: 3
Plot Size: Gross	: 10 x 5 m <sup>2</sup> ,
Net	: 08 x 3 m <sup>2</sup> ,
Fertilizer dose	: 250:115:115 kg N, P <sub>2</sub> O <sub>5</sub> , K <sub>2</sub> O ha <sup>-1</sup> ,
Date of planting	: 07.01.2014
Date of harvesting	: 19.01.2015
Soil Status	: Irrigated, Medium black soil.

### Treatment details:

**No. of Main Treatments:** 05

- 1) V<sub>1</sub> : Co 06001
- 2) V<sub>2</sub> : Co 06002
- 3) V<sub>3</sub> : Co 06022
- 4) V<sub>4</sub> : PI 06032
- 5) V<sub>5</sub> : CoC 671

**No. of Sub Treatments** : 03

- 1) F<sub>1</sub> - 75% RD of N
- 2) F<sub>2</sub> - 100% RD of N
- 3) F<sub>3</sub> - 125% RD of N

### Results:

The data on second year trial for cane and CCS yields, growth observations and quality parameters are presented in Table 1 to 4.

#### Effect of genotypes:

Data presented in Table 1 revealed that the genotype Co 06002 recorded the highest cane (123.81 t ha<sup>-1</sup>) and CCS yield (17.70 t ha<sup>-1</sup>) and was significantly superior to all other genotypes. It was followed by Co 06001 (115.01 t ha<sup>-1</sup> cane and 15.97 t ha<sup>-1</sup> CCS yield).

#### Effect of nitrogen levels:

The nitrogen levels had a non significant effect on cane yield. While significantly the highest CCS yield (16.95 t ha<sup>-1</sup>) was recorded with the application of 125% recommended dose of nitrogen. It was found at par with 100 % recommended dose of nitrogen (15.92 t ha<sup>-1</sup>).

**Effect of interactions:**

The interactions between genotypes and fertilizer levels were found to be non significant for both cane and CCS yields.

**Growth and yield attributes:**

The data regarding growth and yield attributes are presented in Table 2.

**Effect of genotypes:**

The data presented in Table 2 revealed that the effect of genotypes was significant for all the parameters except number of internodes and average cane weight. The genotype Co 06002 recorded significantly the highest germination (70.83 %), tillering ratio (1.76) millable height (286 cm), cane girth (10.0 cm), and millable canes per hectare (104140 ha<sup>-1</sup>). However it was found at par with PI 06032 except millable cane ha<sup>-1</sup>.

**Effect of nitrogen levels:**

Effect of N levels was significant for the tillering ratio, cane girth number of internodes per cane, NMC and average cane weight. Application of 125% recommended dose of nitrogen recorded the highest tillering ratio (1.73), cane girth (10.4 cm), number of internodes per cane (30), and average cane weight (1.21 kg cane<sup>-1</sup>). The application of 100 % recommended N was found at par with 125 % recommended N in respect of tillering ratio, cane girth, number of internodes per cane and average cane weight.

**Effect of interactions:**

The interactions between genotypes and N levels with respect to all the parameter were found to be non significant.

**Quality parameters:**

The genotypes, N levels and their interactions recorded the significant influence on juice quality parameters (Table 3).

The genotype Co 06002 recorded significantly highest brix (22.01), sucrose (19.87%) and purity (92.96%). It was found at par with PI 06032 with respect to brix and sucrose. The CCS percentage was found significantly highest in genotype CoC671, which was found at par with Co-06002.

The application of 125% recommended dose of nitrogen recorded significantly highest brix (21.86), Sucrose (19.91%), Purity (92.68 %) and CCS (14.41%) which was found at par with application of 100% recommended dose of nitrogen.

**Conclusion:**

The genotype Co 06002 was found significantly superior for cane and CCS yields than the other genotypes followed by PI 06032. The application of 125 % recommended dose of nitrogen produced significantly higher CCS yields which was found at par with 100% recommended dose of nitrogen. While cane yield was not affected by different nitrogen levels.

**Project No. AS – 42****Title:** Agronomic Evaluation of promising Sugarcane genotypes (Spring Midlate)

- Objective:**
- 1) To find out the suitable sugarcane genotypes for early spring planting.
  - 2) To find out suitable sugarcane genotypes for highest cane and CCS yield.
  - 3) To find out the suitable fertilizer dose for promising sugarcane genotypes.
  - 4) To find out suitable interaction of promising sugarcane genotypes and fertilizer dose for highest cane and CCS Yield.

**Experimental Details :**

Place	: CSRS, Padegaon,
Design	: Split plot
Replication	: 3
Plot Size: Gross	: 10 x 5 m <sup>2</sup> ,
Net	: 08 x 3 m <sup>2</sup> ,
Fertilizer dose	: 250:115:115 kg N, P <sub>2</sub> O <sub>5</sub> , K <sub>2</sub> O ha <sup>-1</sup> ,
Date of planting	: 13.01.2014
Date of harvesting	: 21.01.2015
Soil Status	: Irrigated, Medium black soil.

**Treatment details :****No. of Main Treatments : 05**

- 1) V<sub>1</sub> : Co 06012
- 2) V<sub>2</sub> : Co 06015
- 3) V<sub>3</sub> : Co 06027
- 4) V<sub>4</sub> : CoM 06082
- 5) V<sub>5</sub> : Co 86032

**No. of Sub Treatments : 03**

- 1) F<sub>1</sub> - 75% RD of N
- 2) F<sub>2</sub> - 100% RD of N
- 3) F<sub>3</sub> - 125% RD of N

**Results:**

The results of second year of the experiment on cane and CCS yields, growth observations and quality parameters are presented in Table 1 to 3.

**Effect of genotypes:**

Data presented in Table 1 revealed that the genotype Co 86032 recorded significantly the highest cane (126.86 t ha<sup>-1</sup>) and CCS (19.25 t ha<sup>-1</sup>) yields. It was followed by Co 06015.

**Effect of nitrogen levels:**

The N levels had a significant effect on cane yield only. Significantly the highest cane (122.63 t ha<sup>-1</sup>) yield was recorded with the application of 125% recommended dose of N. It was found at par with 100% recommended dose of N (117.07 t ha<sup>-1</sup>)

**Effect of interactions:**

The interactions between genotypes and fertilizer levels were found to be non significant for both cane and CCS yields.

**Growth and yield attributes:**

The data regarding growth and yield attributes are presented in Table 2.

**Effect of genotypes:**

The data presented in Table 2 revealed that the effect of genotypes was found significant for all the parameters except cane girth and number of millable canes. The genotype Co 86032 recorded significantly the highest germination (71.48 %), tillering ratio, (1.79), millable height (294 cm), number of internodes per cane (27), and weight per cane (1.29 kg). However, it was at par with Co 06015 in respect of germination percentage, number of internodes per cane and average cane weight.

**Effect of nitrogen levels:**

Effect of N levels was found significant for tillering ratio, cane girth, number of internodes per cane and average cane weight. Application of 125% recommended dose of nitrogen recorded significantly the highest tillering ratio (1.76), cane girth (9.5 cm), number of internodes per cane (29.0) and the average cane weight (1.28 kg) over other levels. It was found at par with 100 % recommended dose of nitrogen for all these parameters.

**Effect of interactions:**

The genotype Co 86032 recorded significantly highest brix (21.97), sucrose (19.87%) and purity (92.17%) which was found at par with Co-06015.

Effect of N levels was found significant for only sucrose and 125% recommended dose of nitrogen recorded the highest sucrose (19.97%), it was found at par with application of 100% recommended dose.

**Quality parameters:**

The genotypes N levels and their interactions did not have significant influence on juice quality parameters (Table 3).

**Conclusion:**

The genotypes Co 86032 recorded significantly higher cane and CCS yields than the other genotypes and it was followed by Co-06015. The application of 125 percent recommended dose of nitrogen produced significantly higher cane yield and found at par with 100 % recommended dose of nitrogen.

**Project No. : AS 66**

**Title : Priming of cane node for accelerating germination.**

**Objective:**

- 1) To find out suitable cane node priming technique.
- 2) To assess the effect of cane node on acceleration of germination

**Experimental details:**

Place	: CSRS, Padegaon,
Design	: Randomized Block Design
Replication	: 4
Plot Size: Gross	: 10 x 6 m <sup>2</sup> ,
Net	: 08 x 4 m <sup>2</sup>
Variety	: Phule 265
Fertilizer dose	: 250:115:115 N: P <sub>2</sub> O <sub>5</sub> : K <sub>2</sub> O kg ha <sup>-1</sup>
Date of planting	: 05.02.2013
Date of harvesting	: 17.01.2015
Soil Status	: Irrigated, Medium black soil.

**Treatments: 6**

T<sub>1</sub> : Un-primed cane node.

T<sub>2</sub> : Treating cane node in hot water in 50°C for 2 hours.

T<sub>3</sub> : Treating cane node in hot water in 50°C and urea solution (3%) for 2 hours

T<sub>4</sub> : Priming cane node with cattle dung, cattle urine and water in 1:2:5 ratio

T<sub>5</sub> : Conventional 3 bud sets planting.

T<sub>6</sub> : Primed and sprouted cane node ( Incubated for four days after priming )

( Put the single cane node in the slurry of cattle dung, cattle urine and water for 15 minutes. take out the buds and put in decomposed FYM and covered it with sugarcane trash for 4-5 days for sprouting.)

**Results :**

The data of second year trial on cane and CCS yields, growth observations and quality parameters of different treatments are presented in Table 1 & 2.

**Effect on cane and CCS yields:**

The data on cane and CCS yields presented in Table 1 revealed that priming cane node with cattle dung plus cattle urine and water in 1:2:5 ratio (T<sub>4</sub>) recorded significantly the highest cane and CCS yield (138.81 and 20.18 t ha<sup>-1</sup>). However, it was at par with treating cane node in hot water in 50°C and urea solution (3%) for 2 hours (T<sub>3</sub>) (133.13 and 19.41 t ha<sup>-1</sup>) significantly lowest cane and CCS yield was observed in unprimed cane node.

**Growth and yield attributes:**

The data regarding growth and yield attributes are presented in Table 2. The germination (74.95%) was found significantly higher with conventional 3 bud sets planting and it was at par with T<sub>4</sub>, T<sub>3</sub> and T<sub>2</sub>. The data revealed that the priming cane node with cattle dung plus cattle urine and water in 1:2:5 ratio (T<sub>4</sub>) recorded

significantly higher tillering ratio (1.73), millable height (314 cm), cane girth (11.60 cm), However, it was at par the treatment treating cane node in hot water in 50°C and urea solution (3%) for 2 hours (T<sub>3</sub>) for tillering ratio (1.68), millable height (305 cm), cane girth (11.10 cm).

The priming cane node with cattle dung plus cattle urine and water in 1:2:5 ratio (T<sub>4</sub>) recorded significantly higher number of internodes (32), number millable canes (106000/ha) and weight per cane (1.31 kg). It was at par with the treating cane node in hot water in 50 °C for 2 hrs (T<sub>2</sub>), treating cane node in hot water in 50 °C and urea solution (3%) for 2 hours (T<sub>3</sub>), conventional 3 bud setts planting (T<sub>5</sub>) and Primed and sprouted cane node ( Incubated for four days after priming) ( T<sub>6</sub>).

#### Quality parameters:

The data regarding juice quality parameters are presented in Table 2 revealed that priming cane node with cattle dung, cattle urine and water in 1:2:5 ratio (T<sub>4</sub>) recorded significantly the highest brix (22.88), sucrose (20.97 %), purity (94.28%) and CCS (14.54 %) than the rest of the treatment.

#### Conclusion:

The priming cane node with cattle dung plus cattle urine and water in 1:2:5 ratio (T<sub>4</sub>) recorded significantly the highest cane and CCS yield (138.81 and 20.18 t ha<sup>-1</sup>). However, it was at par with treating cane node in hot water in 50°C and urea solution (3%) for 2 hours (T<sub>3</sub>) (133.13 and 19.41 t ha<sup>-1</sup>), than the rest of the treatment.

**Project No. AS – 65**

**Title:** Enhancing sugarcane productivity and profitability under Wheat – Sugarcane Cropping system.

**Objectives :** To enhance the productivity of sugarcane under wheat – sugarcane cropping system.

**Experiment details :**

Place : CSRS, Padegaon,  
Design : Randomized Block Design  
Replication : 3  
Plot Size: Gross : 08 x 06 m<sup>2</sup>,  
Net : 06 x 04 m<sup>2</sup>  
Variety : Phule 265  
Date of planting : As per treatment  
Soil Status : Irrigated, Medium black soil.

**Treatment Details : 09**

T1 : Autumn planted sugarcane  
T2 : Autumn planted planted sugarcane + Wheat (1:2)  
T3 : Autumn planted planted sugarcane + Wheat (1:3)  
T4 : Wheat sown on 15<sup>th</sup> November – Late Sugarcane  
T5 : Wheat sown on 15<sup>th</sup> December – Late Sugarcane  
T6 : FIRB sowing of wheat 15<sup>th</sup> November (75 cm with 3 rows of wheat )+ Sugarcane in furrows in third week of February  
T7 : FIRB Sowing of wheat 15<sup>th</sup> November (75 cm with 3 rows of wheat) + Sugarcane in furrows in third week of March  
T8 : FIRB sowing of wheat 15<sup>th</sup> December (75 cm with 3 rows of wheat )+ Sugarcane in furrows in third week of February.  
T9 : FIRB Sowing of wheat 15<sup>th</sup> December (75 cm with 3 rows of wheat) + Sugarcane in furrows in third week of March.

**Result**

The data of second year trial on cane and CCS yield, intercrop yield, biometric observations, quality parameters, monetary returns, cost of cultivation and B:C ratio are presented in Table 1 to 5.

**Cane, CCS and intercrop yields**

Data presented in Table 1 revealed that, cane yield and CCS yield (145.21 t ha<sup>-1</sup> and 20.61 t ha<sup>-1</sup>, respectively) were significantly higher in treatment T<sub>1</sub> (autumn planted Sugarcane) than the rest of the treatments. Regarding intercropping, autumn planted sugarcane + wheat (1:2) (T<sub>2</sub>) produced significantly higher cane yield and CCS yield (135.62 t ha<sup>-1</sup> and 18.54 t ha<sup>-1</sup>, respectively) than other treatments except autumn planted sugarcane + wheat (1:3) (T<sub>3</sub>).

As regards intercrop yield FIRB sowing of wheat 15<sup>th</sup> November (75 cm with 3 rows of wheat) + Sugarcane in furrows in third week of March (T<sub>7</sub>) recorded higher wheat yield (39.16 q ha<sup>-1</sup>) and found at par with FIRB Sowing of wheat 15<sup>th</sup> November (75 cm with 3 rows of wheat) + Sugarcane in furrows in third week of February (T<sub>6</sub>).

**Biometric observations**

The data presented in Table 2 indicated that, the cane girth (10.87) was significantly higher in autumn planted sole sugarcane (T<sub>1</sub>) over rest of the treatments; however, it was on par with treatment T<sub>2</sub>, T<sub>3</sub> and T<sub>4</sub>. Also NMC/ha (99208) was found significantly higher in autumn planted sole sugarcane over rest of the treatments. The growth observations

germination, tillering ratio millable height, number of internodes cane<sup>-1</sup> and weight per cane were found to be non significant.

### Quality parameters

The data presented in Table 3 showed that, there were no significant differences found with respect to quality parameters.

### Economics

The data presented in Table 4 indicated that cane equivalent yield due to different treatments differed significantly. Significantly the highest cane equivalent yield (161.49 t ha<sup>-1</sup>) recorded under autumn planted sugarcane + wheat (1:3) (T<sub>3</sub>) which was at par with autumn planted sugarcane + wheat (1:2) (T<sub>2</sub>) (158.89 t ha<sup>-1</sup>).

The maximum gross monetary returns and net monetary returns were recorded by autumn planted sugarcane + wheat (1:3) (T<sub>3</sub>) (Rs.363350/- and Rs.245452/-, respectively) which was followed by autumn planted sugarcane + wheat (1:2) (T<sub>2</sub>) (Rs.357506/- and Rs.242223/-). The benefit: cost ratio was higher in autumn planted sugarcane + wheat (1:2) (3.10) followed by treatment autumn planted sugarcane + wheat (1:3) (3.08).

### Conclusion

The autumn planted sugarcane produced significantly higher cane yield and CCS yield (145.21 t ha<sup>-1</sup> and 20.61 t ha<sup>-1</sup>, respectively). Under intercropping system, autumn planted sugarcane + wheat (1:2) produced significantly higher cane yield and CCS yield (135.62 t ha<sup>-1</sup> and 18.54 t ha<sup>-1</sup>, respectively). The intercropping of autumn planted sugarcane + wheat (1:2) was found to be more remunerative.

There were no remarkable difference in soil pH, EC, organic carbon and available N,  $\text{P}_2\text{O}_5$  and  $\text{K}_2\text{O}$  content in soil after harvest of sugarcane due to different intercrop combination of wheat there was slight decrease in soil pH, EC, N and increase in available  $\text{K}_2\text{O}$  and soil organic carbon in intercropped plot and no effect on available  $\text{P}_2\text{O}_5$  status after harvest of both the crops

**Title of expt.:** Impact of integrated application of organics and inorganics in improving soil health and sugarcane productivity.

**Objectives:**

To develop nutrient management strategy for sustaining soil health and sugarcane production.

**Experimental details:**

Year of start	: 2014-15	Period of Expt.	: 1 Plant + 2 ratoons
Variety	: CoM 0265(Phule 265)	Season	: Suru
Treatments	: Nine	Replications	: Three
Design	: RBD	Plot size	: 7.2 X 6.0 m
Date of planting	: 30.01.2014	Date of harvesting	: 18.2.2016
Initial Status of Soil	: pH – 7.68, EC – 0.41 dSm <sup>-1</sup> , Organic carbon – 0.69 % Available N – 261 kg ha <sup>-1</sup> , Available P – 23.7 kg ha <sup>-1</sup> , Available K – 268 kg ha <sup>-1</sup> .		

**Treatment details:**

Tr. No	Treatments (Plant cane)
1.	No organic + 50% RDF
2.	No organic + 100% RDF
3.	No organic + RDF as per soil test
4.	FYM @ 20 t ha <sup>-1</sup> + 50 % RDF
5.	FYM @ 20 t ha <sup>-1</sup> + 100 % RDF
6.	FYM @ 20 t ha <sup>-1</sup> + RDF as per soil test
7.	FYM @ 10 t ha <sup>-1</sup> + BF ( Aceto. + PSB) + 50 % RDF
8.	FYM @ 10 t ha <sup>-1</sup> + BF ( Aceto. + PSB) + 100 % RDF
9.	FYM @ 10 t ha <sup>-1</sup> + BF ( Aceto. + PSB) + RDF as per soil test

**Results:**

**a. growth parameters :**

The data in respect of growth parameters was presented in Table 1. The data on germination percentage was found to be nonsignificant, however the significantly higher tillering ratio and cane girth was observed in the treatment T<sub>6</sub> receiving 100 % RDF along with 20 t ha<sup>-1</sup> FYM (2.22 and 9.98 cm, respectively) and it was at par with all other treatments except T<sub>1</sub> receiving 50 % RDF only. The treatment T<sub>6</sub> also recorded significantly higher milleable height (282 cm ) and it was at par with T<sub>9</sub>, T<sub>5</sub>, T<sub>8</sub> and T<sub>4</sub>.

**b. Yield and yield contributing parameters :**

The data in respect of yield and yield contributing parameters presented in Table 1 revealed that the treatment T<sub>6</sub> receiving 100 % RDF along with 20 t ha<sup>-1</sup> FYM recorded significantly the higher average cane weight, number of milleable canes and cane yield (2.05 kg, 91.12 '000 ha<sup>-1</sup> and 186.09 t ha<sup>-1</sup>, respectively) and it was at par with T<sub>9</sub>, T<sub>5</sub>, T<sub>8</sub> and T<sub>4</sub> for average cane weight and cane yield and it was at par with T<sub>5</sub>, T<sub>9</sub>, T<sub>8</sub>, T<sub>4</sub> and T<sub>3</sub>. The treatment T<sub>1</sub> receiving 50 % RDF only recorded the lowest average cane weight, number of milleable canes and cane yield (1.74 kg, 74.88 '000 ha<sup>-1</sup> and 129.76 t ha<sup>-1</sup>, respectively).

The CCS per cent and CCS yield were significantly affected by the different organic and inorganic treatments. The treatment T<sub>6</sub> receiving 100 % RDF along with 20 t ha<sup>-1</sup> FYM only recorded significantly the highest CCS percent and CCS yield

(13.88 % and 25.82 t ha<sup>-1</sup> , respectively) and it was at par rest of the treatments except T<sub>1</sub> receiving 50 % RDF only, T<sub>2</sub> receiving 100 % RDF only and T<sub>3</sub> receiving RDF as per soil test.

**b. Soil chemical properties:**

The soil chemical properties have been analyzed from pre and post harvest soils of sugarcane and presented in Table 2. The soil pH was slightly reduced in all the integrated nutrient management treatments. The lowest soil pH (7.53) was recorded in treatment of T<sub>4</sub> receiving 50 % RDF along with 20 t ha<sup>-1</sup> FYM and found highest in the treatment T<sub>3</sub> receiving RDF as per soil test (7.81). The soil EC was increased in all the treatments over the initials. The significantly lowest EC was noted in the treatment T<sub>1</sub> receiving 50 % RDF and T<sub>2</sub> receiving 100 % RDF only (0.49 dSm<sup>-1</sup>) and it was at par with T<sub>3</sub> receiving RDF as per soil test (0.52 dSm<sup>-1</sup>). The highest soil EC was recorded in treatment T<sub>6</sub> receiving RDF as per soil test along with 20 t ha<sup>-1</sup> FYM (0.65 dSm<sup>-1</sup>) and it was at par with all the integrated nutrient management treatments.

Soil organic carbon content was reduced in the inorganic treatments T<sub>1</sub>, T<sub>2</sub> and T<sub>3</sub> and it was increased in all other all the integrated nutrient management treatments over the initial values. The treatments T<sub>4</sub> receiving 50 % RDF along with 20 t ha<sup>-1</sup> FYM and T<sub>6</sub> receiving RDF as per soil test along with 20 t ha<sup>-1</sup> FYM were recorded significantly the higher organic carbon (0.74 %) and it was at par with T<sub>5</sub>, T<sub>8</sub>, T<sub>9</sub> and T<sub>7</sub>. The lowest organic carbon was recorded in the treatments T<sub>1</sub> receiving 50 % RDF only and T<sub>3</sub> receiving RDF as per soil test (0.66 %).

The treatment T<sub>6</sub> receiving RDF as per soil test along with 20 t FYM recorded significantly the higher available N and available P (318 and 26.5 kg ha<sup>-1</sup>) however, the and significantly higher available K was recorded in the treatment T<sub>5</sub> receiving 100 % RDF along with 20 t ha<sup>-1</sup> FYM (329 kg ha<sup>-1</sup>) followed by T<sub>6</sub> receiving 100 % RDF as per soil test along with 20 t ha<sup>-1</sup> FYM and T<sub>8</sub> receiving 100 % RDF along with 10 t ha<sup>-1</sup> FYM and biofertilizers (319 and 305 t ha<sup>-1</sup>).

**e. Economics:**

The data pertaining to gross returns, net returns and benefit-cost ratio as affected by different treatments are presented in Table No. 3a and 3b. It is revealed from the table 3b that, the application of RDF as per soil test along with 20 t ha<sup>-1</sup> FYM (T<sub>6</sub>) recorded significantly the higher per hectare gross return (Rs.4,18,710 ha<sup>-1</sup>), and followed by T<sub>9</sub> receiving RDF as per soil test along with 10 t ha<sup>-1</sup> FYM + biofertilizers and T<sub>5</sub> receiving 100 % RDF along with 20 t ha<sup>-1</sup> FYM (Rs.4,10,400 and 4,05,383 ha<sup>-1</sup>, respectively) and lowest in the treatment T<sub>1</sub> (Rs.2,91,968 ha<sup>-1</sup>). The treatments T<sub>9</sub> reported significantly the higher per hectare net return (Rs.2,69,901 ha<sup>-1</sup>), and lowest in the treatment T<sub>1</sub> (Rs.1,99,380 ha<sup>-1</sup>). The highest benefit-cost ratio was reported in the treatments T<sub>3</sub> receiving only RDF as per soil test (2.43) and it was found lowest in the treatment T<sub>4</sub> (1.22).

**f. Conclusion:**

The application of recommended dose fertilizers as per soil test along with 20 t ha<sup>-1</sup> FYM for preseasonal sugarcane was found beneficial in terms of yield, quality and soil health.

## B) Completed Experiments

**Project No. AS – 42**

**Title:** Agronomic evaluation of promising sugarcane genotypes (Spring Early)

- Objective:**
- 1) To find out the suitable sugarcane genotypes for early spring planting.
  - 2) To find out suitable sugarcane genotypes for highest cane and CCS yield.
  - 3) To find out the suitable fertilizer dose for promising sugarcane genotypes.
  - 4) To find out suitable interaction of promising sugarcane genotypes and fertilizer dose for highest cane and CCS Yield.

### Experimental Details:

Place	: CSRS, Padegaon,
Design	: Split plot
Replication	: 3
Plot Size: Gross	: 10 x 5 m <sup>2</sup> ,
Net	: 08 x 3 m <sup>2</sup> ,
Fertilizer dose	: 250:115:115 kg N, P <sub>2</sub> O <sub>5</sub> , K <sub>2</sub> O ha <sup>-1</sup> ,
Date of planting	: 19.01.2013, 07.01.2014
Date of harvesting	: 26.01.2014, 19.01.2015
Soil Status	: Irrigated, Medium black soil.

### Treatment details:

**No. of Main Treatments:** 05

- 1) V<sub>1</sub> : Co 06001
- 2) V<sub>2</sub> : Co 06002
- 3) V<sub>3</sub> : Co 06022
- 4) V<sub>4</sub> : PI 06032
- 5) V<sub>5</sub> : CoC 671

**No. of Sub Treatments** : 03

- 1) F<sub>1</sub> - 75% RD of N
- 2) F<sub>2</sub> - 100% RD of N
- 3) F<sub>3</sub> - 125% RD of N

### Results:

The pooled data on two years trial on cane and CCS yields, growth observations and quality parameters are presented in Table 1 to 4.

#### Effect of genotypes:

Data presented in Table 1 revealed that the genotype Co 06002 recorded the highest cane (122.63 t ha<sup>-1</sup>) and CCS yield (16.88 t ha<sup>-1</sup>) and was significantly superior to all other genotypes. It was followed by PI 06032 (113.98 t ha<sup>-1</sup> cane and 15.76 t ha<sup>-1</sup> CCS yield).

#### Effect of nitrogen levels:

The nitrogen levels had a significant effect on both cane and CCS yields. Significantly the highest cane (117.98 t ha<sup>-1</sup>) and CCS (16.47 t ha<sup>-1</sup>) yields were recorded with application of 125% recommended dose of nitrogen. It was followed by 100 % recommended dose of nitrogen with respect to cane yield. CCS yield was found at par with 100% recommended dose of nitrogen.

#### Effect of interactions:

The interactions between genotypes and fertilizer levels were found to be non significant for both cane and CCS yields.

### Growth and yield attributes:

The data regarding growth and yield attributes are presented in Table 2.

#### Effect of genotypes:

The data presented in Table 2 revealed that the effect of genotypes was significant for all the parameters except girth and number of internodes. The genotype, Co 06002 recorded significantly the highest tillering ratio (1.71), millable height (285cm), millable canes per hectare (104020 ha<sup>-1</sup>) and average weight per cane (1.19 kg). However, it was at par with PI 06032 in respect of average weight per cane.

#### Effect of nitrogen levels:

Effect of N levels was found significant for all the parameter except germination and millable cane. Application of 125% recommended dose of nitrogen recorded the highest tillering ratio (1.72), millable height (282 cm), cane girth (10.1 cm), number of internodes per cane (29), and average cane weight (1.17 kg cane<sup>-1</sup>). The application of 100 % recommended N was found at par with 125 % recommended N in respect of tillering ratio, cane height, girth and average cane weight.

#### Effect of interactions:

The interactions between genotypes and N levels with respect to all the parameter were found to be non significant.

#### Quality parameters:

The data presented in Table 3 revealed that the genotype CoC 671 recorded significantly highest brix (21.89) and CCS (13.81%) ,while it was found at par with Co 06002. The nitrogen levels also shorted the significant effects on quality parameters. The application of 125% recommended dose of nitrogen recorded significantly highest brix (21.89), sucrose (19.87%), purity (92.10%) and CCS (13.85%), while brix, sucrose and CCS were found at par with the application of 100% recommended dose of nitrogen.

The interactions effect of the genotypes and N levels did not show any significant influence on juice quality parameters (Table 3).

#### Conclusion:

The genotype Co 06002 was found significantly superior for cane and CCS yields than the other genotypes followed by PI 06032. The application of 125 % recommended dose of nitrogen produced significantly higher cane and CCS yields followed by 100 % recommended dose of nitrogen.

## Project No. AS – 42

**Title:** Agronomic Evaluation of promising Sugarcane genotypes (Spring Midlate)

- Objective:**
- 1) To find out the suitable sugarcane genotypes for early spring planting.
  - 2) To find out suitable sugarcane genotypes for highest cane and CCS yield.
  - 3) To find out the suitable fertilizer dose for promising sugarcane genotypes.
  - 4) To find out suitable interaction of promising sugarcane genotypes and fertilizer dose for highest cane and CCS Yield.

### Experimental Details :

Place	: CSRS, Padegaon,
Design	: Split plot
Replication	: 3
Plot Size: Gross	: 10 x 5 m <sup>2</sup> ,
Net	: 08 x 3 m <sup>2</sup> ,
Fertilizer dose	: 250:115:115 kg N, P <sub>2</sub> O <sub>5</sub> , K <sub>2</sub> O ha <sup>-1</sup> ,
Date of planting	: 19.01.2013, 13.01.2014
Date of harvesting	: 27.01.2014 21.01.2015
Soil Status	: Irrigated, Medium black soil.

### Treatment details :

**No. of Main Treatments :** 05

- 1) V<sub>1</sub> : Co 06012
- 2) V<sub>2</sub> : Co 06015
- 3) V<sub>3</sub> : Co 06027
- 4) V<sub>4</sub> : CoM 06082
- 5) V<sub>5</sub> : Co 86032

**No. of Sub Treatments :** 03

- 1) F<sub>1</sub> - 75% RD of N
- 2) F<sub>2</sub> - 100% RD of N
- 3) F<sub>3</sub> - 125% RD of N

### Results:

The pooled results of the two years of the experiment on cane and CCS yields, growth observations and quality parameters are presented in Table 1 to 3.

#### Effect of genotypes:

Data presented in Table 1 revealed that the genotype Co 86032 recorded significantly the highest cane (122.78 t ha<sup>-1</sup>) yield. It was followed by Co 06015. The effect of genotypes on CCS yield was found to be non significant.

#### Effect of nitrogen levels:

The perusal of data shown in table I revealed that the N levels had non significant effect on both cane and CCS yields.

#### Effect of interactions:

The interactions between genotypes and fertilizer levels were found to be non significant for both cane and CCS yields.

### **Growth and yield attributes:**

The data regarding growth and yield attributes are presented in Table 2.

### **Effect of genotypes:**

The data presented in Table 2 revealed that the effect of genotypes was found significant for all the parameters except number of millable canes and average cane weight. The genotype Co 86032 recorded significantly the highest germination (70.97 %), tillering ratio (1.80), millable height (293 cm), cane girth (9.41 cm), number of internodes per cane (25), and weight per cane (1.28 kg). However, it was at par with Co 06015 in respect of germination percentage, and cane girth, number of internodes and average cane weight.

### **Effect of nitrogen levels:**

Effect of N levels was significant for the tillering ratio, girth, number of internodes per cane and average cane weight. Application of 125% recommended dose of nitrogen recorded significantly the highest tillering ratio (1.73), cane girth (9.61cm) number of internodes per cane (28.0) and the average cane weight (1.28 kg) over other levels. It was found at par with 100 % recommended dose of nitrogen for all these parameters except number of internodes.

### **Effect of interactions:**

The interactions between genotypes and nitrogen levels in respect of all the parameter were found to be non significant.

### **Quality parameters:**

The data presented in Table 3 revealed that the genotype Co 86032 recorded significantly higher brix (22.03), sucrose (19.78%) and purity (91.42%) it was found at par with Co-06015 with respect to sucrose and purity.

### **Conclusion:**

The genotypes Co 86032 recorded significantly higher cane yield than the other genotypes and it was followed by Co-06015. The application of different levels of of nitrogen shown non significant results with respect to cane and CCS yields.

**Project No. : AS 66**

**Title : Priming of cane node for accelerating germination.**

**Objective:** 1. To find out suitable cane node priming technique.

1. To assess the effect of cane node on acceleration of germination

**Experimental details:**

Place	: CSRS, Padegaon,
Design	: Randomized Block Design
Replication	: 4
Plot Size: Gross	: 10 x 6 m <sup>2</sup> ,
Net	: 08 x 4 m <sup>2</sup>
Variety	: Phule 265
Fertilizer dose	: 250:115:115 N: P <sub>2</sub> O <sub>5</sub> : K <sub>2</sub> O kg ha <sup>-1</sup>
Date of planting	: 25.02.2012, 16.02.2013, 05.12.2013
Date of harvesting	: 07.03.2013, 30.01.2014, 17.01.2015
Soil Status	: Irrigated, Medium black soil.

**Treatments: 6**

T<sub>1</sub> : Un-primed cane node.

T<sub>2</sub> : Treating cane node in hot water in 50°C for 2 hours.

T<sub>3</sub> : Treating cane node in hot water in 50°C and urea solution (3%) for 2 hours

T<sub>4</sub> : Priming cane node with cattle dung, cattle urine and water in 1:2:5 ratio

T<sub>5</sub> : Conventional 3 bud setts planting.

T<sub>6</sub> : Primed and sprouted cane node ( Incubated for four days after priming )

( Put the single cane node in the slurry of cattle dung, cattle urine and water for 15 minutes. take out the buds and put in decomposed FYM and covered it with sugarcane trash for 4-5 days for sprouting.)

**Results :**

The pooled mean data of 3 year trials on cane and CCS yields, growth observations and quality parameters of different treatments are presented in Table 1 and 2.

**Effect on cane and CCS yields:**

The data on cane and CCS yields presented in Table 1 revealed that priming cane node with cattle dung plus cattle urine and water in 1:2:5 ratio (T<sub>4</sub>) recorded significantly the highest cane and CCS yield (135.43 and 17.82 t ha<sup>-1</sup>). However, cane yield was found at par with treating cane node in hot water in 50°C and urea solution (3%) for 2 hours (T<sub>3</sub>) ( 131.63 t ha<sup>-1</sup>) and CCS yield was found at par with treating cane node in hot water in 50°C and urea solution (3%) for 2 hours (T<sub>3</sub>) (17.28 t ha<sup>-1</sup>), treating cane node in hot water in 50°C for 2 hours (T<sub>2</sub>) (16.46 t ha<sup>-1</sup>) and conventional 3 bud setts planting (T<sub>5</sub>) (16.33 t ha<sup>-1</sup>). The lowest cane and CCS yield was observed in unprimed cane node.

**Growth and yield attributes:**

The data regarding growth and yield attributes are presented in Table 2. The perusal of data revealed that the conventional 3 bud setts planting (T<sub>5</sub>) recorded significantly higher germination (73.17%) However, it was at par the priming cane node

with cattle dung plus cattle urine and water in 1:2:5 ratio (T<sub>4</sub>) (72.67), treating cane node in hot water in 50°C and urea solution (3%) for 2 hours (T<sub>3</sub>) (69.96).

The priming cane node with cattle dung plus cattle urine and water in 1:2:5 ratio (T<sub>4</sub>) recorded significantly higher tillering ratio (1.74), It was found at par with the treatment treating cane node in hot water in 50°C and urea solution (3%) for 2 hours (T<sub>3</sub>). The number millable canes(109000/ha) are recorded significantly higher in the priming cane node with cattle dung plus cattle urine and water in 1:2:5 ratio (T<sub>4</sub>) and found at par with the rest of the treatments except un-primed cane node (T<sub>1</sub>) and Primed and sprouted cane node (Incubated for four days after priming) (T<sub>6</sub>). The millable height (306 cm), cane girth (11.2 cm) and the weight per cane (1.24 kg) recorded numerically highest in the priming cane node with cattle dung plus cattle urine and water in 1:2:5 ratio (T<sub>4</sub>).

#### **Quality parameters:**

The data regarding juice quality parameters are presented in Table 2 revealed that priming cane node with cattle dung, cattle urine and water in 1:2:5 ratio (T<sub>4</sub>) recorded significantly the highest brix (22.44), sucrose (20.54 %) and CCS (14.38 %). than the rest of the treatment. While CCS per cent was found at par with treatment T<sub>3</sub>

#### **Conclusion:**

The priming cane node with cattle dung plus cattle urine and water in 1:2:5 ratio (T<sub>4</sub>) recorded significantly the highest cane and CCS yield (135.43 and 17.82 t ha<sup>-1</sup>) and the cane yield was at par with treating cane node in hot water in 50°C and urea solution (3%) for 2 hours (T<sub>3</sub>) ( 131.63 t ha<sup>-1</sup>), CCS yield was found at par with treatment T<sub>3</sub>, T<sub>2</sub> and T<sub>5</sub>. The lowest cane and CCS yield was observed in unprimed cane node.
